<sup>&</sup>lt;sup>2</sup> This WILKENING 84 value includes a finite-size effect and a magnetic effect.

<sup>&</sup>lt;sup>3</sup> This WILKENING 84 value is more cautious than the other and excludes the finite-size effect, which relies on uncertain nuclear integrals.

• • • We do not use the following data for averages, fits, limits, etc. • • •

$11.7 \pm 0.8 \pm 0.7$	<sup>5</sup> BARANOV	01	RVUE	Global average
$12.5 \pm 0.6 \pm 0.9$	MACGIBBON	95	CNTR	$\gamma p$ Compton scattering
$9.8 \pm 0.4 \pm 1.1$	HALLIN	93	CNTR	$\gamma p$ Compton scattering
$10.62 {+ 1.25 + 1.07 \atop - 1.19 - 1.03}$	ZIEGER	92	CNTR	$\gamma  {\it p}$ Compton scattering
$10.9 \pm 2.2 \pm 1.3$	<sup>6</sup> FEDERSPIEL	91	CNTR	$\gamma p$ Compton scattering

- $^1$  BEANE 03 uses effective field theory and low-energy  $\gamma p$  and  $\gamma d$  Compton-scattering data. It also gets for the isoscalar polarizabilities (see the erratum)  $\alpha_{\mbox{\it N}}=(13.0\pm 1.9^{+3.9}_{-1.5})\times 10^{-4}~{\rm fm}^3$  and  $\beta_{\mbox{\it N}}=(-1.8\pm 1.9^{+2.1}_{-0.9})\times 10^{-4}~{\rm fm}^3$ .
- <sup>2</sup>BLANPIED 01 gives  $\alpha_p + \beta_p$  and  $\alpha_p \beta_p$ . The separate  $\alpha_p$  and  $\beta_p$  are provided to us by A. Sandorfi. The first error above is statistics plus systematics; the second is from the model.
- <sup>3</sup> This OLMOSDELEON 01 result uses the TAPS data alone, and does not use the (reevaluated) sum-rule constraint that  $\alpha + \beta = (13.8 \pm 0.4) \times 10^{-4}$  fm<sup>3</sup>. See the paper for a discussion.
- <sup>4</sup> MACGIBBON 95 combine the results of ZIEGER 92, FEDERSPIEL 91, and their own experiment to get a "global average" in which model errors and systematic errors are treated in a consistent way. See MACGIBBON 95 for a discussion.
- <sup>5</sup> BARANOV 01 combines the results of 10 experiments from 1958 through 1995 to get a global average that takes into account both systematic and model errors and does not use the theoretical constraint on the sum  $\alpha_p + \beta_p$ .
- <sup>6</sup> FEDERSPIEL 91 obtains for the (static) electric polarizability  $\alpha_p$ , defined in terms of the induced electric dipole moment by  ${\bf D}=4\pi\epsilon_0\alpha_p{\bf E}$ , the value  $(7.0\pm2.2\pm1.3)\times10^{-4}~{\rm fm}^3$ .

### p MAGNETIC POLARIZABILITY $\beta_p$

The electric and magnetic polarizabilities are subject to a dispersion sumrule constraint  $\overline{\alpha}+\overline{\beta}=(14.2\pm0.5)\times10^{-4}~{\rm fm^3}$ . Errors here are anticorrelated with those on  $\overline{\alpha}_p$  due to this constraint.

#### p CHARGE RADIUS

This is the rms electric charge radius,  $\sqrt{\langle r_E^2 \rangle}$ .

See below for the background. There are in fact three kinds of measurements of the proton radius: with atomic hydrogen, with electron scattering off of hydrogen, and with muonic hydrogen. The earlier face-off seemed to be between the two electronic methods and muonic hydrogen. But a purely statistical reanalysis of electron scattering data by HIGIN-BOTHAM 16 finds consistency with muonic hydrogen—and now it "is the atomic hydrogen results that are the outliers."

Most measurements of the radius of the proton involve electron-proton interactions, and most of the more recent values agree with one another. The most precise of these is  $r_p=0.879(8)$  fm (BERNAUER 10). The CODATA 14 value (MOHR 16), obtained from the electronic results, is 0.8751(61). Compared to this CODATA value, however, a measurement using muonic hydrogen finds  $r_p=0.84087(39)$  fm (ANTOGNINI 13), which is 16 times more precise but differs by 5.6 standard deviations (using the CODATA 14 error).

Since POHL 10 (the first  $\mu p$  result), there has been a lot of discussion about the disagreement, especially concerning the modeling of muonic hydrogen. Here is an incomplete list of papers: DERUJULA 10, CLOET 11, DISTLER 11, DERUJULA 11, ARRINGTON 11, BERNAUER 11, HILL 11, LORENZ 14, KARSHENBOIM 14A, and PESET 15.

Until the difference between the  $e\,p$  and  $\mu\,p$  values is understood, it does not make sense to average the values together. For the present, we give both values. It is up to workers in this field to solve this puzzle.

See our 2014 edition (Chinese Physics **C38** 070001 (2014)) for values published before 2003.

#### p MEAN LIFE

A test of baryon conservation. See the "p Partial Mean Lives" section below for limits for identified final states. The limits here are to "anything" or are for "disappearance" modes of a bound proton (p) or (n). See also the  $3\nu$  modes in the "Partial Mean Lives" section. Table 1 of BACK 03 is a nice summary.

LIMIT (years)	PARTICLE	CL%	DOCUMENT ID		TECN	COMMENT
>5.8 × 10 <sup>29</sup>	n	90	<sup>1</sup> ARAKI	06	KLND	$n \rightarrow \text{invisible}$

- $^{
  m 1}$  ARAKI 06 looks for signs of de-excitation of the residual nucleus after disappearance of
- a neutron from the s shell of  $^{12}{\rm C.}$   $^2$  AHMED 04 looks for  $\gamma$  rays from the de-excitation of a residual  $^{15}{\rm O}^*$  or  $^{15}{\rm N}^*$  following the disappearance of a neutron or proton in  $^{16}$ O.
- $^3$  BACK 03 looks for decays of unstable nuclides left after N decays of parent  $^{12}$ C,  $^{13}$ C,  $^{16}\text{O}$  nuclei. These are "invisible channel" limits.
- <sup>4</sup> ZDESENKO 03 gets this limit on proton disappearance in deuterium by analyzing SNO data in AHMAD 02.
- 5 AHMAD 02 (see its footnote 7) looks for neutrons left behind after the disappearance of the proton in deuterons.
- <sup>6</sup> BERNABEI 00B looks for the decay of a  $\frac{128}{53}$ I nucleus following the disappearance of a proton in the otherwise-stable  $\frac{129}{54}$ Xe nucleus.
- $^7$  EVANS 77 looks for the daughter nuclide  $^{129}$ Xe from possible  $^{130}$ Te decays in ancient Te ore samples.
- <sup>8</sup> This mean-life limit has been obtained from a half-life limit by dividing the latter by ln(2)
- <sup>9</sup> FLEROV 58 looks for the spontaneous fission of a <sup>232</sup>Th nucleus after the disappearance of one of its nucleons.

#### **P** MEAN LIFE

Of the two astrophysical limits here, that of GEER 00D involves considerably more refinements in its modeling. The other limits come from direct observations of stored antiprotons. See also "p Partial Mean Lives" after "p Partial Mean Lives," below, for exclusive-mode limits. The best (lifetime/branching fraction) limit there is  $7 \times 10^5$  years, for  $\overline{p} \rightarrow e^- \gamma$ . We advance only the exclusive-mode limits to our Summary Tables.

LIMIT (years)	CL%	<u>EVTS</u>	DOCUMENT ID		TECN	COMMENT
• • • We do not	use the	following	data for averages	, fits,	limits, et	.c. • • •
$>$ 8 $\times$ 10 <sup>5</sup>	90		<sup>1</sup> GEER	<b>00</b> D		$\overline{p}/p$ ratio, cosmic rays
>0.28			GABRIELSE	90	TRAP	Penning trap
>0.08	90	1	BELL	79	CNTR	Storage ring
$>1$ $\times$ 10 <sup>7</sup>			GOLDEN	79	SPEC	$\overline{p}/p$ ratio, cosmic rays
$> 3.7 \times 10^{-3}$			BREGMAN	78	CNTR	Storage ring

 $<sup>^{1}</sup>$  GEER 00D uses agreement between a model of galactic  $\overline{p}$  production and propagation and the observed  $\overline{p}/p$  cosmic-ray spectrum to set this limit.

#### **p** DECAY MODES

See the "Note on Nucleon Decay" in our 1994 edition (Phys. Rev. **D50**, 1173) for a short review.

The "partial mean life" limits tabulated here are the limits on  $\tau/B_i$ , where au is the total mean life and B<sub>i</sub> is the branching fraction for the mode in question. For N decays, p and n indicate proton and neutron partial lifetimes.

	Mode	Partial mean life (10 <sup>30</sup> years)	Confidence level
		Antilepton + meson	
$ au_1$	$N  ightarrow e^+ \pi$	> 2000 (n), > 8200 (p)	90%

### P PARTIAL MEAN LIVES

The "partial mean life" limits tabulated here are the limits on  $\tau/B_i$ , where  $\tau$  is the total mean life for the proton and  $B_i$  is the branching fraction for the mode in question.

Decaying particle: p= proton, n= bound neutron. The same event may appear under more than one partial decay mode. Background estimates may be accurate to a factor of two.

 $<sup>^{</sup>m 1}$  In estimating the background, this HIRATA 89C limit (as opposed to the later limits of WALL 00B and MCGREW 99) does not take into account present understanding that the flux of  $\nu_{\mu}$  originating in the upper atmosphere is depleted. Doing so would reduce the background and thus also would reduce the limit here.

<sup>&</sup>lt;sup>4</sup>We have converted half-life to 90% CL mean life.

### **P** PARTIAL MEAN LIVES

The "partial mean life" limits tabulated here are the limits on  $\overline{\tau}/B_i$ , where  $\overline{\tau}$  is the total mean life for the antiproton and  $B_i$  is the branching fraction for the mode in question.
